Highly transparent fibre core: $n=1.500$, radius $r$; cladding index $n'=1.400$. Semiconductor laser S, on the axis extension, emits a beam of half-angle 30°. To admit all the light, a spherical cap QAQ′ of radius $R$, of the core material, is sintered at its end. The figure omits the cladding. S is a point source; the fibre is in air, with index $n_0$ taken as 1.000.

1. For the whole beam to reach the cap, what condition must distance $x$ from source S to A satisfy?
2. For $R=1.8r$, S–A separation $R$, axis angle $\alpha$: for $\alpha$ at $\alpha_1=30°$、$\alpha_2=25°$ and $\alpha_3=20°$, can each of the three rays propagate in the fibre by total internal reflection?

2. (20 points)

Use relativistic energy and momentum to analyse and justify the following.

1. A photon colliding with a free electron at rest in vacuum cannot have its energy fully absorbed.
2. A photon on a metal can be fully absorbed, ejecting an electron by the photoelectric effect.

3. (25 points)

Shown wooden wedge OABC ($M=30.0$kg) rests on level ground; AB has slope $\beta=60°$, and BC slope $\alpha=45°$. A very short smooth arc joins AB, BC at B. Release a point block, $m=4.00$kg, from rest at A, height $h_1=2.80$m above ground. It slides without friction on the wedge. Maximum static and sliding ground friction have coefficients $\mu=6.00\times10^{-2}$. The height of B above the table is $h_2=2.00$m. Ignore both speed changes at B. Find work done on the wedge from A to the bottom C by the sliding block. Take $g=10.0\text{m/s}^2$.
